Deposition landform

1. Alluvial plain
2. Flood plain
3. Natural leavy
4. delta.

Landforms of depositions:

Flood Plain

1. Floodplain is a major landform of river deposition.
2. Fine sized materials like sand, silt and clay are carried by relatively slow moving waters in gentler channels and are found in the plains
3. In plains, channels shift laterally and change their courses occasionally

Natural levees

1. They are found along the banks of large rivers.
2. They are low, linear and parallel ridges of coarse deposits along the banks of rivers
3. Point bars are also known as meander bars.

Landforms of depositions:

Deltas

1. Deltas are like alluvial fans but develop at a different location.
2. The load carried by the rivers is dumped and spread into the sea.
3. If this load is not carried away far into the sea or distributed along the coast, it spreads and accumulates as a low cone.
4. Unlike in alluvial fans, the deposits making up deltas are very well sorted with clear stratification.
5. The coarsest materials settle out first and the finer fractions like silts and clays are carried out into the sea. As the delta grows, the river distributaries continue to increase in length and delta continues to build up into the sea.

Types of Delta: Arcuate Delta, Cuspate Delta, Bird-foot Delta.

Nile river delta

Ebro river delta

Mississippi river delta

Landforms of deposition: Natural Levee

Formation of river terraces

1. **River terraces** are surfaces marking old valley floor or floodplain levels.
2. River terraces are basically **products of erosion** as they result due to vertical erosion by the **stream into its own depositional floodplain**.
3. There can be a **number of such terraces at different heights** indicating former river bed levels.
4. The river terraces may occur at the same elevation on either side of the rivers in which case they are called **paired terraces**.

Landforms of deposition: Natural Levee

Formation of river terraces

1. **River terraces** are surfaces marking old valley floor or floodplain levels.

Masses of ice moving as sheets over the land (continental glacier or piedmont glacier if a vast sheet of ice is spread over the plains at the foot of mountains) or as linear flows down the slopes of mountains in broad trough-like valleys (mountain and valley glaciers) are called glaciers

dnyaneshwar.mogal.ias@gmail.com(8421928891)

The movement of glaciers is slow unlike water flow.

The movement could be a few centimetres to a few metres a day or even less or more.

Glaciers move basically because of the force of gravity.

Erosion by glaciers is tremendous because of friction caused by sheer weight of the ice.

LevelUp IAS

1. The material plucked from the land by glaciers (usually large-sized angular blocks and fragments) get dragged along the floors or sides of the valleys and cause great damage through abrasion and plucking.
2. Glaciers can cause significant damage to even unweathered rocks and can reduce high mountains into low hills and plains.
3. As glaciers continue to move, debris gets removed, divides get lowered and eventually the slope is reduced to such an extent that glaciers will stop moving leaving only a mass of low hills and vast outwash plains along with other depositional features.

**Horns (Pyramidal
Peak) and Serrated
Ridges (Arete)**

**Glacial
Valleys/Troughs:
Hanging Valley and
U Shaped Valley**

Pyramidal peak/Horn, Arete / Serrated Ridge

1. **Arete:** When two Corries cut back on the opposite side of the mountain a Knife-edged ridge/ Zigzag Ridge are formed called Arete or Serrated Ridge
2. **Horn:** When 3/more cirques cut back together they form angular horn or pyramidal peak.

The Matterhorn, part of the Alps in Switzerland, is a

U shaped Valley

- Glacier on the downward journey fed by ice from several Corries like tributaries that join a river begins to wear away the sides and the floor of valley down
- It straightens any protruding spur on its course and the interlock spurs are blunted to form truncated spurs
- A U shaped valley is formed because of this process.
- After the disappearance of the ice, glacial valley may be filled with water forming Ribbon Lake

Hanging Valley

- The main valley is eroded much rapidly than the tributary valleys
- After the ice has melted, a tributary valley therefore hangs above the main valley.
- Such tributary valleys are termed as hanging valley

Moraine

Moraine: Long ridges of deposit of glacier till.

- **Terminal moraines:** Long ridges of debris deposited at the end (toe) of the glaciers.
- **Lateral moraines:** Formed along the sides parallel to the glacial valleys. The lateral moraines may join a terminal moraine forming a horse-shoe shaped ridge
- **Medial Moraine:** The moraine in the centre of the glacial valley flanked by lateral moraines
- **Recessional Moraine:** Deposition of end moraine may be in several succeeding waves, as the ice may melt back by stages forming a series of moraine

Outwash Plain

- Small amount of rock debris are small enough to be carried by the streams formed by the melting glaciers are called as glaciofluvial deposits
- Such glaciofluvial deposits are called outwash deposits
- Unlike till deposits, the outwash deposits are roughly stratified and assorted
- Melt water sort and re-deposits the material in variety of form
- When the deposition takes the form of alternating ridges and depressions the later may contain kettle lakes and give rise to knob and kettle topography

Depositional L-f	Till	Outwash Plain.
	1. deposition by glacier 2. Not sorted 3. Boulder, Rocks & small pebbles exist side by side.	1. Deposition by river & glacier 2. Sorted. 3. Boulder, Rocks & pebbles are layered acc to size

Till Plain

- The **unsorted** coarse and fine debris dropped by melting glacier is called as glacial till
- Most of the rock fragments in the angular to sub angular
- It is spread in sheets and not mounds
- Form Till Plain
- Landform is monotonous and featureless

Esker

They are long narrow sinuous ridges composed of sand and gravel

They mark the former site of subglacial meltwater streams

They may be few feet in height but are several miles long

they are made up of highly porous sand and gravel so water is rapidly drained off from their crest

Drumlin

They are smooth Oval shaped features composed of glacial till along with gravel and sand

The long axis of drumlin are parallel to the direction of the ice movement so drumlin indicate the direction of glacier movement

One end of the drumlin facing the glacier are called stoss end which is a blunter and steeper than the other end

The stoss end gets blunter due to pushing by the moving ice

The other end is called as tail

Egg basket topography

Waves

Waves:

Waves are disturbances or ripples formed overseas surface as energy moves from one place to another. Do not involve movement of water particles it is the only the energy which moves. Formed when producing force remains smaller than the resisting force due to which the energy is carry the water particle and and 's only successful in creating disturbances

Norway

Costal land forms

Erosional Landforms

1. **Wave-cut cliffs** is one of the most dominant erosional landform
2. Almost all sea cliffs are steep
3. At the foot of such cliffs there may be a flat or gently sloping platform covered by rock debris derived from the sea cliff behind. Such platforms occurring at elevations above the average height of waves is called a wavecut terrace.

Cave

1. The lashing of waves against the base of the cliff and smashing of rock against the cliff create hollows and these hollows get widened and deepened to form caves. As the roofs of caves collapse and sea cliffs recede further inland, the flat top of the cliff may leave a plateau.

Climate

(14) Composition of Atmosphere and Layering

Climate :

1. Atmosphere.
2. Temperature
3. Pressure
4. Humidity
5. Precipitation ex rainfall, snowfall, grizzles.
6. Wind ex sea wind , trade wind , monsoon wind,
7. Extreme event cyclone, cloud bust, heat wave cold wave.

Atmosphere: blank of the gasses that surround the earth. It is composed of gasees dust particles water vapors pollutant, ions, nitrogen, oxygen. Helium.

Atmosphere

ionosphere
 $H_2, N_2,$
 O_2, He

Dnyaneshwar mogal

dnyaneshwar.mogal.ias@gmail.com

Composition of atmosphere:

Element of climate.

el Up 

- Permanent gas are

1. For most inner planets hydrogen and helium remain in the gases form due to high temperature. And continuous event of solar flare blows the gas away to outer planet.
2. Earth is at a suitable distance here carbon dioxide get the chance to settle down in the ocean and from $\text{CO}_2 + \text{H}_2\text{O}$ also called carbonic acid.

Phases of evolution of atmosphere:

1. Earth been the hot nebula with pre mordial atmosphere composed of hydrogen and helium
2. Loss of pre mordial atmosphere because of effect of solar wind.
3. The degassing stage. And the release of carbon dioxide, water vapour and ammonia
4. The cycle of evaporation cooling of water vapor condensation and precipitation in this process the water droplet the dissolve the CO_2 which accumulates in form of ocean water.

5. Ammonia strikes by the UV rays to split into nitrogen and hydrogen.
 6. Hydrogen gas evaporates and nitrogen continues to build up.
 7. Stage of formation of oxygen; in the ocean with the formation of life like cyno bacteria co₂ is utilized and the oxygen is released as by product once the ocean water is saturated as a biproduct oxygen becomes the part of atmosphere.
-

dnyaneshwar.mogal.ias@gmail.com(8421928891)

Other → Argon, Hydrogen, Helium, Water vapours, etc.

- It has major gases like Nitrogen, Oxygen
- It has minor gases like argon, carbon dioxide, helium, hydrogen, ozone
- Permanent gas are Nitrogen, Oxygen, argon
- Variable gas are carbon dioxide, ozone, water vapor (1% to 4%: D

1. Nitrogen oxygen and argon do not directly play a important role in various climatic processes like wind rain fall as they are not greenhouse gases.
2. Green house gases are those that observe the heat ex, methane, Co₂ ozone. Etc.

3. Layer of atmosphere based the changes in the temperature.

Structure of the atmosphere

1. It refers to structure in the way atmosphere is organized and how the layers in the atmosphere is arranged
2. There are three ways of studying the Earth's atmosphere layering
 1. Temperature pattern
 2. Density Variation
 3. Relative mixing

Layering of the atmosphere:

It refers to structure in the way atmosphere is organized how the layer are arranged. There can be 3 ways of layering

On the basis of temperature pattern.

On the basis of relative mixing

On the basis of density variation.

Atmospheric layering on the basis of density variation.

-
1. Atmosphere has weight and it is compressible. Nealy 50% of atmosphere within 5.6 km.
 2. 90 % within the 16km
 3. 99% atmosphere are within the 30km.
-

Layering on the basis of Density

- Why we have higher density in lower layer and why with height density reduces?
- **Reasons:** Atmosphere as weight and is compressible

Layering

- 50% of entire atmosphere is within 5.6 km
- Entire atmosphere is within 100 km
- 99% of entire atmosphere is within 30 km

Layering on the basis of Relative Mixing

- Based on relative homogeneity
- Much of the atmosphere is very well mixed and atmosphere despite being mixture it acts as a single layer.
- Atmosphere is divided into two layers where is no physical mixing.
- Within the first 10 km of atmosphere is called HOMOSPHERE.
- Within 10 km, mixing is very good for major gases (oxygen, nitrogen, etc.)
- Beyond 80 km, the atmosphere separates out into different layers.

Heterosphere:

- Lower Layers: N_2 molecules and N ion, O ion and $Particulate$ molecules

Layering on the basis of relative mixing:

1. Much of the atmosphere is very well mixed despite being the mixture of gases it act as one single layer of gas. This is seen in the first 80 km it is called in homosphere.
2. Above 80 km the gases and iron are separated out on the basis of their weight. This is called as hetrosphere.
3. The lower layer have the nitrogen molecules and nitrogen iron along with oxygen ions and oxygen molecules while upper layers have hydrogen and helium molecules.
4. Layer on the basis of temperature pattern.
5. The layers are troposphere, stratosphere, mesosphere, thermosphere, exosphere.
6. The temperature reduces with increasing in height in troposphere, increasing in stratosphere, reduces in the mesosphere, increases in thermosphere& exosphere.

Heating mechanisms in the atmosphere.

1. Atmosphere that surrounds the earth surface is heated in the two ways
2. observation of the UV rays by the ozone layer in troposphere
3. observation of the long wave radiation from the earth surface by the greenhouse gases. (long wave terrestrial radiation infra ray radiation)
4. Gamma x ultra visible infra micro radio.

5. Greenhouse gases are transparent to incoming solar radiation but are opaque to the outgoing terrestrial radiation. The lower atmosphere heated to process of conduction (transfer of heat) convection (lower surface heated first it will move to upper) and advection (heat is travelling horizontally heatwave).

Green house gases

1. Carben dioxide
2. Methane
3. Nitrogen
4. Nitrous oxide
5. Hydrofluorocarbons
6. Perfluorocarbon
7. Sulfur hexafluoride

8. Nitrogen trifluoride.
 9. Ozone
 10. HCFC.
-

1. Carbon dioxide
2. Methane
3. Nitrous oxide
4. Hydrofluorocarbons (HFCs)
5. Perfluorocarbons (PFCs)
6. Sulfur hexafluoride (SF_6)
7. Nitrogen trifluoride (NF_3)
8. Ozone
9. HCFC

Q. which of the following is correct.

1. The amount of insulation received at the equator is roughly 10 times more than pole.
 2. Infrared radiation constitutes 2/3 rd of the insulation.
 3. Infrared radiation is largely observed by the water vapor that is concentrated at the lower atmosphere.
 4. infrared radiations are part of visible spectrum of electromagnetic radiation
-

The answer is 3. Because UVI Ultra and visible spectrum contains 63 percent and infrared contains 37 percent not approx. 1/3 b is wrong the insulation is more at the equator but not 10 times.

Layer of atmosphere on the basis of temperature pattern.

Troposphere.

1. The temperature reduces with the increase in the height as troposphere is heated from the below outgoing long wave terrestrial radiation.
2. The rate of cooling is 1-degree Celsius per 165 m or 6.4 degrees Celsius per km this is called as normal lapse rate
3. The height of troposphere is 8 km at pole and 18 km at the equator, the average height is 13 km.
4. Thickness is greater at the equator because heat is transported to greater height by the conventional air currents, the air packet rises up to great height before it starts turning away. Troposphere word is derived from trop which means turning away.
5. The troposphere is also called convective region, since all the convection is stopped at tropopause.

- 6.
7. A
8. Troposphere experience fall in temperature the temperature is -80°C at the equator at the tropopause. While at pole temperature is -45°C at the tropopause.

- 9.
 10. A
 11. Meteorologically this most significant layer as the entire atmosphere and near all the weather phenomena like cyclone, rainfall, fog, Hellstrom, are confined to this layer.
 12. Above the troposphere the temperature is constant in tropopause, therefore tropopause acts as lid and holds all the circulation within the tropopause.
 13. All the Jet planes and aero planes fly in the tropopause in the lower stratosphere.
-

(15) Atmosphere Layering and Heat Budget

This

Layering of Atmosphere on the basis of temperature: T, S, M, T. It is based on heating pattern by insolation and terrestrial radiation

PV/T is not constant in the atmosphere PV/T is constant in the close system or close glass. In the real world pT is constant in the p is inversely proportional to temperature.

Troposphere

1. Temperature falls with the increase in height. Temp is **-80 degree Celsius** on EQ while **-45 degree** at Poles on Tropopause.
2. **Meteorologically:** Most significant zone. Entire atmosphere (all weather phenomena like cyclones, rainfall, fog and hailstorm etc. are confined to this layer)
3. This layer **contains dust particles** and water vapor
4. Above the troposphere, there is **tropopause** where the temperature is constant
5. **Tropopause** acts as a lid. It hold all the circulations within the tropopause
6. All the jets and aeroplanes fly in **tropopause** or in lower stratosphere

The diagram shows a cross-section of the atmosphere with altitude on the y-axis (0 to 20 km / 0 to 10 miles) and temperature on the x-axis. Key features labeled include:

- Troposphere**: The bottom layer where temperature decreases with altitude. It contains "Cumulonimbus Cloud", "Stratocumulus Clouds", and "Commercial Jet".
- Tropopause**: The boundary between the troposphere and stratosphere, where temperature is constant.
- Stratosphere**: The layer above the tropopause where temperature increases with altitude. It contains "Polar Stratospheric Clouds", "Ozone Layer", and "Spy Plane".
- Other labels**: "Weather Balloon", "Blue Jet", and "Mount Everest" are also shown.

LevelUp IAS
Troposphere
 To exit full screen, press Esc

1. Temperature falls with the increase in height. Temp is **-80 degree Celsius on EQ** while **-45 degree at Poles on Tropopause**.
2. **Meteorologically:** Most significant zone. Entire atmosphere (all weather phenomena like cyclones, rainfall, fog and hailstorm etc. are confined to this layer)
3. This layer **contains dust particles** and water vapor
4. Above the troposphere, there is **tropopause** where the **temperature is constant**
5. **Tropopause acts as a lid**. It holds all the circulations within the troposphere
6. All the jets and **aeroplanes fly in tropopause** or in lower stratosphere

Stratosphere:

1. It is layer above the troposphere
2. Temperature increases with increase in the height
3. temperature reaches zero degree Celsius at 50 km. rise of temperature is due to present of ozone which observe infrared ray incoming and reflecting from surfaces.
4. This layer is almost free from the cloud and therefore the Aeroplane fly in this layer. (plane can also fly in the tropopause)

5. In the stratopause the temperature is constant with increasing in height.
 6. Ozone molecules and Ozone gas present throughout the stratosphere that is 10 km to 50 km but there is buildup of Ozone between 20-30 km as UV rays' tends to split the ozone molecules up from 50 km to 30 km, and the terrestrial infrared radiation split the ozone molecules from the lowest stratosphere up to 20km.
-

Mesosphere:

1. It lies above the stratosphere and extends up to 80km.
 2. Most meteors burn in this layer on entering space. Cause friction.
 3. The temperature drops with increasing altitude up to mesopause. The temperature is -45 degrees Celsius and the mesopause is the coldest layer in the atmosphere. As the air is very cold even very scarce water vapor can condense into mesospheric cloud called noctilucent cloud.
-

Thermosphere:

1. In this layer the temperature rises rapidly with increasing in height because of radiation from the sun. (heated from the above) its extents between 80 – 400 km. though the temperature is very high any object and person in this layer does feel the heat because the atmosphere is very rarefied that is gas molecules are spaces 100km apart.
 2. The international space station and satellites orbit in this layer. The auroras are observed in the lower part of this layer.
 3. The Karman line is located at an altitude of 100 km and used to define boundary between the space and earth's atmosphere.
-

Ionosphere:

1. The ultraviolet and x ray solar radiation ionizes the atom and molecules creating the layer of ions called ionosphere.

2. Ionosphere plays important role for depleting the radio wave for communication
 3. Discovery of the ionosphere was made by the author Kennelly and Oliver Heaviside who explain the transmission of radio wave signal around the curved earth surface therefore the ions rich layer also refers as Kennelly Heaviside layer.
 4. Ionosphere has many layer D,E,F .
 5. D is the lowest layer and it reflects the long wavelength radio wave and allows short and medium wavelength radio wave.
 6. E layer reflects the medium wave radio wave and extends from 90-160 km
 7. F layer reflects the short-wave radio wave and extends from 160-300 km
-

Exosphere:

1. From the above the 400 km atmosphere is very rarefied
 2. The temperature increases with increase in height.
 3. It has light gases, and it considers space.
-

LevelUp IAS
2011

The jet aircrafts fly very easily and smoothly in the lower stratosphere. What could be the appropriate explanation

1. There are no clouds or water vapour in the lower stratosphere.
2. There are no vertical winds in the lower stratosphere.

Which of the statements given above is/are correct in context?

(a) 1 only
(b) 2 only
(c) Both 1 and 2
(d) Neither 1 nor 2

al.ias@gmail.com

The answer is c because no clouds and water vapor less disturbance.

And in the troposphere, there is air conventional current so vertical wind meaning plane are stable and low fuel.

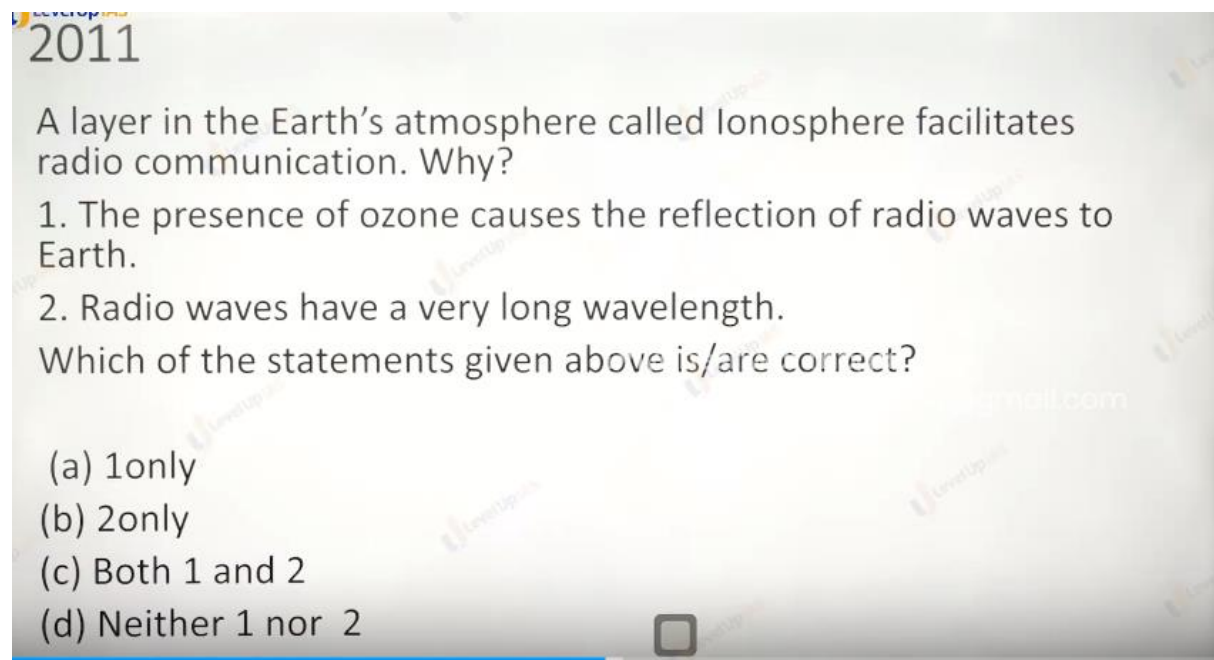

2011

A layer in the Earth's atmosphere called Ionosphere facilitates radio communication. Why?

1. The presence of ozone causes the reflection of radio waves to Earth.
2. Radio waves have a very long wavelength.

Which of the statements given above is/are correct?

(a) 1 only
(b) 2 only
(c) Both 1 and 2
(d) Neither 1 nor 2

Option d

Ozone is present in the stratosphere.

For 2 short medium and long wavelength all are reflected. Cause of ions

Not because of the long wavelength of radio.

2012

dryaneshwar.mogal.ias@gmail.com(8421928891)

Normally, the temperature decreases with the increase in height from the Earth's surface, because:

1. The atmosphere can be heated upwards only from the Earth's surface.
2. There is more moisture in the upper atmosphere.
3. The air is less dense in the upper atmosphere.

Select the correct answer using the codes given below:

- (a) 1 only
- (b) 2 and 3 only
- (c) 1 and 3 only
- (d) 1, 2 and 3

Only c.

1 is obviously true and for 3 is somewhere true less molecule's small chance of getting heated.

2 moisture is less in the upper atmosphere as height increases.

Mains Question: UPSC CSE 2022

- Troposphere is a very significant atmosphere layer that determines weather processes. How?

Temperature → pressure → winds 1.

Climate : Heat budget , temperature pattern.

Heat budget.

HEAT BUDGET

1. Earth's surface and Earth's atmosphere has variation in temperature but on an average Earth's atmosphere temperature is around 15-17 degree Celsius.
2. Earth's atmosphere has been capable of maintaining its average temperature
3. Earth is not getting progressively hotter and does not get progressively cooler so Earth is considered to be efficient heat engine (something that absorbs energy, does some work and releases heat energy later).
4. This can be depicted by Heat Budget. (Budget is a statement that helps to appreciate how heat energy comes in and how energy is lost)
5. There are two parts of understanding the Heat Budget.

The diagram illustrates the Earth's heat budget. It shows incoming solar radiation (yellow arrows) from the sun. Some radiation is reflected by clouds (labeled 'Reflected by Clouds') and some is reflected by the surface (labeled 'Reflected by Surface'). Radiation absorbed by clouds is labeled 'Absorbed by Clouds'. Radiation absorbed by the surface is labeled 'Absorbed by Surface'. The surface also emits infrared radiation (labeled 'Infrared Radiation Emitted by Surface'). The atmosphere absorbs and emits radiation (labeled 'Absorption and Emission by Atmospheric Gases, Water Vapor, and Dust'). The net emission from the surface is shown as a green arrow (labeled 'Net Emission from Surface'). The emission by clouds is shown as a green arrow (labeled 'Emission by Clouds'). The emission by water vapor and CO2 is shown as a green arrow (labeled 'Emission by Water Vapor, CO2').

1. The earth's surface and the earth's atmosphere has variation in the temperature but on an average the earth's atmospheric temperature 15 to 17 degrees Celsius.
2. Earth's atmosphere has been capable of maintaining the average temperature i.e. earth is not getting progressively warmer and progressively cooler. So, the earth is efficient heat engine. This maintenance of temperature can be defected by the heat budget.
3. Budget is a statement where it can be appreciated how energy comes and how the energy goes.
4. There are two components to heat budget
 - a. Incoming solar radiation and outgoing radiation.

HEAT BUDGET

1. Earth's surface and Earth's atmosphere has variation in temperature but on an average Earth's atmosphere temperature is around 15-17 degree Celsius.
2. Earth's atmosphere has been capable of maintaining its average temperature
3. Earth is not getting progressively hotter and does not get progressively cooler so Earth is considered to be efficient heat engine (something that absorbs energy, does some work and releases heat energy later).
4. This can be depicted by Heat Budget. (Budget is a statement that helps to appreciate how heat energy comes in and how energy is lost)
5. There are two parts of understanding the Heat Budget:
 - a. Incoming solar radiation and outgoing radiation.

The diagram illustrates the Earth's heat budget with the following components and energy flows:

- Incoming Solar Radiation:** Represented by a yellow sun icon on the left.
- Reflected by Clouds:** Red arrows pointing from the sun to the clouds.
- Reflected by Surface:** Red arrows pointing from the sun to the Earth's surface.
- Absorbed by Clouds:** Red arrows pointing from the sun to the clouds.
- Absorbed by Water Vapor, Dust, O₃:** Red arrows pointing from the sun to the atmosphere.
- Absorbed by Surface:** Red arrows pointing from the sun to the Earth's surface.
- Outgoing Radiation:** A bracketed group of green arrows on the right side of the diagram.
 - Net Emission from Surface:** A green arrow pointing away from the surface.
 - Emission by Clouds:** A green arrow pointing away from the clouds.
 - Emission by Water Vapor, CO₂:** A green arrow pointing away from the atmosphere.
- Absorption and Emission by Atmospheric Gases, Water Vapor, and Dust:** A green arrow pointing from the surface to the atmosphere.
- Infrared Radiation Emitted by Surface:** A green arrow pointing from the surface to the atmosphere.

Influx component:

1. In flux 100 units are received from the solar radiation nearly 35% reflected (albedo reflectivity) 27% from the cloud 2 by the earth surface and 6 from the atmosphere.
2. 14 unit is observed by the ozone. And 51 units are observed by the earth's surface.

Outflux component.

1. 17 units are radiated from the earth's surface directly to space.
2. The earth's surface transfer heat via radiation convection and condensation.
3. Surface to earth's atmosphere radiation losses is 6 units.
4. Turbulence and convection transfer are 9 units.
5. From earth's surface to earth's atmosphere condensation related transfer are 19 unit
6. The units received by the atmosphere is $9 + 19 + 6 = 34$ Units.
7. Atmosphere sends 34 units to space. The 14 units observed by the ozone layer are sent to space by does completing the heat budget.

Heat budget :

1. heat receive is not lost instantaneously, the energy receive is observed and work is done, in formed of biological and other

physical processes this manifest in the form of climate and weather conditions.

2. Despite the earth atmosphere in the being balance there are places which are net receiver of energy, and there are places where energy is deficits.
 3. The low latitude are latitudes of energy surplus while high latitude are energy deficits.
 4. The internal latitudinal exchanges drives the atmosphere and ocean waterflow.

C

Answer: c

Sample Albedos of Earth

<u>Surface</u>	<u>Typical albedo</u>
Fresh asphalt	0.04
Open ocean	0.06
Worn asphalt	0.12
Conifer forest (Summer)	0.08, 0.09 to 0.15
Deciduous trees	0.15 to 0.18
Bare soil	0.17
Green grass	0.25
Desert sand	0.4
New concrete	0.55
Ocean ice	0.5–0.7
Fresh snow	0.80–0.90

2022

Q. Consider the following statements :

1. High clouds primarily reflect solar radiation and cool the surface of the Earth.
2. Low clouds have a high absorption of infrared radiation emanating from the Earth's surface and thus cause warming effect.

Which of the statements given above is/are correct ?

(a) 1 only
(b) 2 only
(c) Both 1 and 2
(d) Neither 1 nor 2

D. low cloud are thicker enough to reflect the more and it is white.so lower cloud reflect the more heat that high cloud.

And high cloud will observer more (don't know.)

Role of cloud in warming and cooling the earth.

1. The low clouds primarily reflect the solar radiation and cool the surface of the earth.
 2. High cloud observes the infrared the from the earth surface and thus have warming the planet.

Mains Question: 2013

Q) What do you understand by the phenomenon of 'temperature inversion' in meteorology? How does it affect the weather and the inhabitants of the place?
